

Week 1 Graded Quiz

TOTAL POINTS 15

1. Relational databases are based on which mathematical theory or field?

1 point

- Set theory
- Matrix algebra
- Information theory
- Probability theory

2.

1 point

YearsInBusiness in the ER diagram above is a:

- Composite attribute
- Unique attribute
- Candidate key
- Derived attribute

3.

1 point

Which of the following is true about cardinality constraints on the relationship between Doctor and Outpatient Location depicted in this ER diagram?

- A doctor is required to work at one outpatient location, but can work at no more than 1 outpatient location.
- An outpatient location must have 1 doctor working at it, but can have no more than 1 doctor working at it.
- A doctor can work at many outpatient locations, but does not have to work at any.
- An outpatient location must have at least 1 doctor working at it, but can have many doctors working at it.

4.

1 point

DOCTOR
<u>LicenseNo</u>
<u>State</u>
DoctorName
YrReceivedMD

Which columns would be necessary for identifying unique doctors in the doctor table of the database built from the relational schema excerpt above?

- You would have to use both LicenseNo and State
- State
- LicenseNo
- You could use either LicenseNo or State

5.

1 point

In the ER diagram above, Doctor_ID and OL_ID are called:

- Foreign keys
- Composite attributes or keys
- Unique attributes
- Primary keys

6. Which type of information is most likely to be stored in a relational database as opposed to another type of database?

1 point

- Tweets
- Metadata (file name, file location, when the file was created, etc.) about pictures
- Pictures
- Texts

7.

1 point

What can you infer about the data being collected based on the relational schema above?

- A doctor can work at many outpatient locations, and an outpatient location can have many doctors working at it
- The data collected in OL_ID of the WorksAt table, on its own, is sufficient to determine at which outpatient location(s) each doctor works
- The data collected in OL_ID of the OutpatientLocation table, on its own, is sufficient to determine at which outpatient location(s) each doctor works
- A doctor can only work at one outpatient location, but an outpatient location can have many doctors working at it

8.

1 point

Based on the diagram above, which attribute(s) can be used to identify unique books?

- BookName and EditorID
- BookName
- BookName and BookPubDate

9. Which of the following statements are true about foreign keys? Check all that apply. (Note that you will need to select more than one correct response to answer this question correctly.) 1 point

- Foreign keys allow information in different tables to be linked to each other
- Foreign keys are columns with unique values for every row in the relation/table they are in
- Foreign keys refer to columns with unique values for every row in other relations/tables
- Foreign keys always have the same name as at least one primary key in another table

10.

1 point

Given the relational schema presented above, how many tables would you need to use in order to determine the outpatient location(s) a doctor named "Karen Smith" works at?

- 2
- 2 or 3, depending on the strategy you use to combine the information
- 3
- 1

11.

1 point

Which of the following is true about cardinality constraints on the relationship between Doctor and Outpatient Location depicted in this ER diagram?

- A doctor is required to work at one outpatient location, but can work at no more than 1 outpatient location.
- Each outpatient location must have 1 doctor working at it, but can have no more than 1 doctor working at it.
- A doctor can work at many outpatient locations, but does not have to work at any.
- An outpatient location must have at least 1 doctor working at it, but can have many doctors working at it.

12. Which of the following statements are true about **the technical terms** (as opposed to the common terms) for the concepts represented by relational schemas? 1 point

- The technical term for items in a relational schema that become columns in a real database is "attributes."
- The technical term for items in a relational schema that become columns in a real database is "fields"
- The technical term for items in a relational schema that become tables in a real database is "entities"

13.

1 point

Based on the diagram above, which of the following is true?

- ShowType and ShowName are needed together to provide a unique identifier for each show
- ShowDate and ShowVenue are needed together to provide a unique identifier for each show
- ShowType and ShowVenue are needed together to provide a unique identifier for each show
- ShowID and ShowVenue are needed together to provide a unique identifier for each show

14.

1 point

If this relational schema represented a database that was already implemented, what columns would you use to combine the information in the transactions table with the information in the departinfo table?

- "deptname" to connect the transactions table to the deptinfo table
- "store" to connect the transactions table to the storeinfo table, and then "deptname" to connect the storeinfo table to the deptinfo table
- "sku" to connect the transactions table to the skuinfo table, and then "deptID" to connect the skuinfo table to the deptinfo table
- "sku" to connect the transactions table to the skuinfo table, and then "deptname" to connect the skuinfo table to the deptinfo table

15. For relational databases to work most efficiently, which of the following requirements of set theory should be followed? Check all that apply. (Note that you will need to select more than one correct response to answer this question correctly.)

1 point

- Each row in a table should represent a unique instance of the information in that table
- Each column in a table should represent a unique category of information
- Single tables should represent the smallest logical parts of a data set
- There should be no NULL values allowed in the database
